Membrane Distillation Seminar ppt. MD is a thermally driven process, in which water vapour transport occurs through a non wetted porous hydrophobic membrane. The term MD comes from the similarity between conventional distillation process and its membrane variant as both technologies are based on the vapour-liquid equilibrium for separation and both of them require the latent heat of evaporation for the phase change from liquid to vapour which is achieved by heating the feed solution.

An Introduction to Membrane Distillation

Membrane Distillation (MD) is one of the emerging nonisothermal membrane separation processes, which refers to a thermally driven transport of vapor through nonwetted porous hydrophobic membranes, the driving force being the vapor pressure difference between the two sides of the membrane pores.

Membrane Distillation | ScienceDirect

Membrane distillation is a thermally driven separation process in which separation is driven by phase change. A hydrophobic membrane presents a barrier for the liquid phase, allowing the vapour phase to pass through the membrane's pores. The driving force of the process is a partial vapour pressure difference commonly triggered by a temperature difference.

Basics of Membrane Technology

Membrane distillation uses hydrophobic membranes to separate pure distillate water from warm water. Water vapour is transported through the membrane due to a pressure difference caused by the difference in temperature. Because the MD module houses a range of evaporation stages as part of an

Membrane distillation (MD) is a separation process where a micro-porous hydrophobic membrane separates two aqueous solutions at different temperatures. The hydrophobicity of the membrane prevents mass transfer of the liquid, whereby a gas-liquid interface is created.

Membrane Distillation Ppt typically do not involve a phase change and therefore do not involve a specific heat of vaporization (like distillation) or a specific heat of crystallization (like crystallization). Because there is no phase change, highly selective membranes can, in a number of circumstances, accomplish separations with considerably less energy than other
